

Static Routing

At the end of this episode, I will be able to:

1. Static routing

Leamer Objective: *Learn about static routing, both its purpose and typical configurations*

Description: In this episode, you will learn about static routing in modern networks. This episode includes the need for static routing as well as typical configurations of these routing instructions.

-
- Static routing refers to the process of manually entering routing instructions into the memory of routing devices - this is an alternative to dynamic routing protocols that can share routing instructions with other devices in an automated fashion
 - There are many potential uses for static routing in your network, including:
 - Static routing is used to define a "default route" - this route defines an exit point from the router when another more specific entry is not available
 - Static routing might be used in a very small network where dynamic routing is not needed
 - Static routing might be used as a backup to dynamic routing
 - There are some benefits to static routing - including low overhead on the device, simplicity, and full control over packet movements
 - Here is an example static route from a Cisco device. Notice this static route entry sends traffic destined for the 10.10.10.0/24 network to the next hop device at 172.16.1.2:
ip route 10.10.10.0 255.255.255.0 172.16.1.2
